

## AN ASYMPTOTICALLY TIGHT BOUND ON THE $Q$ -INDEX OF GRAPHS WITH FORBIDDEN CYCLES

Vladimir Nikiforov

*Communicated by Slobodan Simić*

ABSTRACT. Let  $G$  be a graph of order  $n$  and let  $q(G)$  be the largest eigenvalue of the signless Laplacian of  $G$ . It is shown that if  $k \geq 2$ ,  $n > 5k^2$ , and  $q(G) \geq n + 2k - 2$ , then  $G$  contains a cycle of length  $l$  for each  $l \in \{3, 4, \dots, 2k + 2\}$ . This bound on  $q(G)$  is asymptotically tight, as the graph  $K_k \vee \overline{K}_{n-k}$  contains no cycles longer than  $2k$  and

$$q(K_k \vee \overline{K}_{n-k}) > n + 2k - 2 - \frac{2k(k-1)}{n+2k-3}.$$

The main result gives an asymptotic solution to a recent conjecture about the maximum  $q(G)$  of a graph  $G$  with forbidden cycles. The proof of the main result and the tools used therein could serve as a guidance to the proof of the full conjecture.

### 1. Introduction

Given a graph  $G$ , the  $Q$ -index of  $G$  is the largest eigenvalue  $q(G)$  of its signless Laplacian  $Q(G)$ . In this note we give an asymptotically tight upper bound on  $q(G)$  of a graph  $G$  of a given order, with no cycle of specified length. Let us start by recalling a general problem in spectral extremal graph theory:

*How large can  $q(G)$  be if  $G$  is a graph of order  $n$ , with no subgraph isomorphic to some forbidden graph  $F$ ?*

This problem has been solved for several classes of forbidden subgraphs; in particular, in [9] it has been solved for forbidden cycles  $C_4$  and  $C_5$ . In addition, it seems a folklore result that  $q(G) > n$  implies the existence of  $C_3$ , and this bound is exact in view of the star of order  $n$ . For longer cycles, a general conjecture has been stated in [9], which we reiterate next to clarify the contribution of the present note.

---

2010 *Mathematics Subject Classification*: 15A42; 05C50.

*Key words and phrases*: signless Laplacian; maximum eigenvalue; forbidden cycles; spectral extremal problems.

Let  $S_{n,k}$  be the graph obtained by joining each vertex of a complete graph of order  $k$  to each vertex of an independent set of order  $n - k$ ; in other words,  $S_{n,k} = K_k \vee \overline{K}_{n-k}$ . Also, let  $S_{n,k}^+$  be the graph obtained by adding an edge to  $S_{n,k}$ .

CONJECTURE 1. *Let  $k \geq 2$  and let  $G$  be a graph of sufficiently large order  $n$ . If  $G$  has no  $C_{2k+1}$ , then  $q(G) < q(S_{n,k})$ , unless  $G = S_{n,k}$ . If  $G$  has no  $C_{2k+2}$ , then  $q(G) < q(S_{n,k}^+)$ , unless  $G = S_{n,k}^+$ .*

Conjecture 1 seems difficult, but not hopeless. It is very likely that it will be solved completely in the next couple of years. Thus, one of the goals of this note is to make some suggestions for such a solution and to emphasize the relevance of some supporting results.

The starting point of our work is the observation that both  $q(S_{n,k})$  and  $q(S_{n,k}^+)$  are very close to  $n + 2k - 2$  whenever  $n$  is large. In fact, the difference between these values is  $\Omega(1/n)$ , as can be seen from the following proposition.

PROPOSITION 2. *If  $k \geq 2$  and  $n > 5k^2$ , then*

$$n + 2k - 2 - \frac{2(k^2 - k)}{n + 2k + 2} > q(S_{n,k}^+) > q(S_{n,k}) > n + 2k - 2 - \frac{2(k^2 - k)}{n + 2k - 3}.$$

These bounds prompt a weaker, yet asymptotically tight version of Conjecture 1, which we shall prove in this note.

THEOREM 3. *Let  $k \geq 2$ ,  $n > 6k^2$ , and let  $G$  be a graph of order  $n$ . If  $q(G) \geq n + 2k - 2$ , then  $G$  contains cycles of length  $2k + 1$  and  $2k + 2$ .*

Before going further, let us note a corollary of Theorem 3.

COROLLARY 4. *Let  $k \geq 2$ ,  $n > 6k^2$ , and let  $G$  be a graph of order  $n$ . If  $q(G) \geq n + 2k - 2$ , then  $G$  contains a cycle of length  $l$  for each  $l \in \{3, 4, \dots, 2k + 2\}$ .*

Indeed, if  $l \geq 5$ , the conclusion follows immediately from Theorem 3. For  $l \in \{3, 4\}$ , recall the bound  $q(G) \leq \max\{d_u + d_v : \{u, v\} \in E(G)\}$ . In view of  $q(G) \geq n + 2$ , there must be an edge  $\{u, v\}$  belonging to two triangles; hence  $G$  contains both  $C_3$  and  $C_4$ .

Even though Theorem 3 is weaker than Conjecture 1, our proof is not too short. To emphasize its structure, we have extracted a few important points into separate statements, which we give next.

LEMMA 5. *If  $G$  is a graph with no  $P_{2k+1}$ , then for each component  $H$  of  $G$ , either  $v(H) = 2k$  or  $e(H) \leq (k - 1)v(H)$ .*

Write  $K_{2k} + v$  for the graph obtained by joining a vertex  $v$  to a single vertex of the complete graph  $K_{2k}$ .

LEMMA 6. *Let  $v$  be a vertex of a graph  $G$  of order  $n$ . If  $G$  contains no  $P_{2k+1}$  with both endvertices different from  $v$ , then  $2e(G) - d_v \leq (2k - 1)(n - 1)$ , unless  $G$  is a union of several copies of  $K_{2k}$  and one  $K_{2k} + v$ .*

We also need bounds on  $q(G)$  for some special classes of graphs. Since the known upper bounds did not work in these cases, we came up with a few technical results giving the required bounds.

LEMMA 7. *Let the integers  $k, p, m$ , and  $n$  satisfy*

$$k \geq 2, m \geq 1, p \geq 0, n = 2kp + m, n \geq 6k + 13.$$

*Let  $H$  be a graph of order  $m$  and let  $F$  be the union of  $p$  disjoint graphs of order  $2k$ , which are also disjoint from  $H$ . Let  $G$  be the graph obtained by taking  $F \cup H$  and joining some vertices of  $F$  to a single vertex  $w$  of  $H$ . If*

$$(1) \quad q(H) \leq m + 2k - 2 + \frac{6pk}{n + 3},$$

*then  $q(G) \leq n + 2k - 2$ , with equality holding if and only if equality holds in (1).*

The reason for Lemma 7 being so technical is that it must support the proof of the following two quite different corollaries.

COROLLARY 8. *Let  $k, p$ , and  $n$  be integers such that  $k \geq 2, p \geq 0$ , and  $n = 2(p+1)k+2$ . Let  $G = K_1 \vee ((pK_{2k}) \cup K_{2k+1})$ . If  $n \geq 6k+13$ , then  $q(G) < n+2k-2$ .*

Given a graph  $G$  and  $u \in V(G)$ , write  $G-u$  for the graph obtained by removing the vertex  $u$ .

COROLLARY 9. *Let  $k \geq 2$ ,  $G$  be a graph of order  $n$ , and  $w \in V(G)$ . Suppose that for each component  $C$  of  $G-w$ , either  $v(C) = 2k$  or  $e(C) \leq (k-1)v(C)$ . If  $n \geq 6k+13$ , then  $q(G) < n+2k-2$ .*

In the next section we outline some notation and results needed in our proofs. The proofs themselves are given in Section 3.

## 2. Notation and supporting results

For graph notation and concepts undefined here we refer the reader to [2]. For introductory and reference material on the signless Laplacian see the survey of Cvetković [5] and its references. In particular, let  $G$  be a graph, and  $X$  and  $Y$  be disjoint sets of vertices of  $G$ . We write:

- $V(G)$  for the set of vertices of  $G$ ,  $E(G)$  for the set of edges of  $G$ , and  $e(G)$  for  $|E(G)|$ ;
- $G[X]$  for the graph induced by  $X$ , and  $e(X)$  for  $e(G[X])$ ;
- $e(X, Y)$  for the number of edges joining vertices in  $X$  to vertices in  $Y$ ;
- $\Gamma_u$  for the set of neighbors of a vertex  $u$ , and  $d_u$  for  $|\Gamma_u|$ .

We write  $P_k$ ,  $C_k$ , and  $K_k$  for the path, cycle, and complete graph of order  $k$ .

Given a graph  $G$  and a vertex  $u \in V(G)$ , note that

$$\sum_{v \in \Gamma_u} d_v = 2e(\Gamma_u) + e(\Gamma_u, V(G) \setminus \Gamma_u).$$

Below we shall use this fact without reference.

**2.1. Some useful theorems.** Here we state several known results, all of which are used in the proof of Theorem 3. We start with two classical theorems of Erdős and Gallai [7].

**THEOREM 10.** *Let  $k \geq 1$ . If  $G$  is a graph of order  $n$ , with no  $P_{k+2}$ , then  $e(G) \leq kn/2$ , with equality holding if and only if  $G$  is a union of disjoint copies of  $K_{k+1}$ .*

**THEOREM 11.** *Let  $k \geq 2$ . If  $G$  is a graph of order  $n$ , with no  $C_{k+1}$ , then  $e(G) \leq k(n-1)/2$ , with equality holding if and only if  $G$  is a union of copies of  $K_k$ , all sharing a single vertex.*

For connected graphs Kopylov [10] has enhanced Theorem 10 as follows.

**THEOREM 12.** *Let  $k \geq 1$ , and let  $G$  be a connected graph of order  $n$ .*

(i) *If  $n \geq 2k+2$  and  $G$  contains no  $P_{2k+2}$ , then*

$$e(G) \leq \max \left\{ kn - k(k+1)/2, \binom{2k}{2} + (n-2k) \right\};$$

(ii) *If  $n \geq 2k+3$  and  $G$  contains no  $P_{2k+3}$ , then*

$$e(G) \leq \max \left\{ kn - k(k+1)/2 + 1, \binom{2k+1}{2} + (n-2k-1) \right\}.$$

We refer the reader to the more recent paper [1], where the conditions for equality in Kopylov's bounds are determined as well.

We shall use the following sufficient condition for Hamiltonian cycles, proved by Ore [13].

**THEOREM 13.** *If  $G$  is a graph of order  $n \geq 3$  and  $e(G) > \binom{n-1}{2} + 1$ , then  $G$  has a Hamiltonian cycle.*

The following structural extension of Theorem 10 has been established in [12].

**THEOREM 14.** *Let  $k \geq 1$  and let the vertices of a graph  $G$  be partitioned into two sets  $A$  and  $B$ . If  $2e(A) + e(A, B) > (2k-1)|A| + k|B|$ , then there exists a path of order  $2k+1$  with both endvertices in  $A$ .*

We finish this subsection with two known upper bounds on  $q(G)$ . The proof of Theorem 3 will be based on a careful analysis of the following bound on  $q(G)$ , which can be traced back to Merris [11]. The case of equality was established in [8].

**THEOREM 15.** *For every graph  $G$ ,*

$$q(G) \leq \max \left\{ d_u + \frac{1}{d_u} \sum_{v \in \Gamma_u} d_v : u \in V(G) \right\}.$$

*If  $G$  is connected, equality holds if and only if  $G$  is regular or semiregular bipartite.*

Finally, let us mention the following corollary, due to Das [6].

THEOREM 16. *If  $G$  is a graph with  $n$  vertices and  $m$  edges, then*

$$q(G) \leq \frac{2m}{n-1} + n - 2,$$

*with equality holding if and only if  $G$  is either complete, or is a star, or is a complete graph with one isolated vertex.*

In the next section we prove our main results.

### 3. Proofs

In the proofs given below there are several instances where the bounds can be somewhat improved at the price of more involved arguments and calculations. Such improvements seem not too worthy unless geared towards the complete solution of Conjecture 1. Instead, we tried to keep the exposition concise, so that the main points are more visible.

PROOF OF PROPOSITION 2. It is known that

$$q(S_{n,k}) = \frac{1}{2} \left( n + 2k - 2 + \sqrt{(n + 2k - 2)^2 - 8(k^2 - k)} \right).$$

Hence, we see that

$$\begin{aligned} q(S_{n,k}) - (n + 2k - 2) &= -\frac{4(k^2 - k)}{n + 2k - 2 + \sqrt{(n + 2k - 2)^2 - 8(k^2 - k)}} \\ &> -\frac{2(k^2 - k)}{n + 2k - 3}, \end{aligned}$$

and also

$$q(S_{n,k}) - (n + 2k - 2) < -\frac{2(k^2 - k)}{n + 2k - 2}.$$

To bound  $q(S_{n,k}^+)$  let  $\mathbf{x} = (x_1, \dots, x_n)$  be a unit eigenvector to  $q(S_{n,k}^+)$  and let  $x_1, \dots, x_k$  be the entries corresponding to the vertices of degree  $n - 1$  in  $S_{n,k}^+$ . Let  $k + 1$  and  $k + 2$  be the vertices of the extra edge of  $S_{n,k}^+$ . By symmetry,  $x_1 = \dots = x_k$  and  $x_{k+1} = x_{k+2}$ . Using the eigenequations for  $Q(G)$  and the fact that

$$q(S_{n,k}^+) > q(S_{n,k}) > n + 2k - 2 - \frac{2(k^2 - k)}{n + 2k - 3} > n + k - 1,$$

we see that

$$x_{k+1}^2 = \frac{k^2 x_1^2}{(q(S_{n,k}^+) - k - 2)^2} < \frac{k}{(q(S_{n,k}) - k - 2)^2} < \frac{k}{(n - 3)^2}.$$

Next, comparing the quadratic forms  $\langle Q(S_{n,k}^+) \mathbf{x}, \mathbf{x} \rangle$  and  $\langle Q(S_{n,k}) \mathbf{x}, \mathbf{x} \rangle$  of the matrices  $Q(S_{n,k}^+)$  and  $Q(S_{n,k})$ , we see that

$$\begin{aligned} q(S_{n,k}^+) - (x_{k+1} + x_{k+2})^2 &= \langle Q(S_{n,k}^+) \mathbf{x}, \mathbf{x} \rangle - (x_{k+1} + x_{k+2})^2 \\ &= \langle Q(S_{n,k}) \mathbf{x}, \mathbf{x} \rangle \leq q(S_{n,k}). \end{aligned}$$

Thus, after some algebra, we get

$$\begin{aligned} q(S_{n,k}^+) &< q(S_{n,k}) + \frac{4k}{(n-3)^2} < n + 2k - 2 - \frac{2(k^2 - k)}{n + 2k - 2} + \frac{4k}{(n-3)^2} \\ &< n + 2k - 2 - \frac{2(k^2 - k)}{n + 2k + 2}, \end{aligned}$$

completing the proof of Proposition 2.  $\square$

PROOF OF LEMMA 5. Let  $H$  be a component of  $G$ . Set  $m = v(H)$  and assume that  $m \neq 2k$ . We shall show that  $e(H) < (k-1)m$ . If  $m \leq 2k-1$ , then

$$e(H) \leq \binom{m}{2} = \frac{m(m-1)}{2} \leq (k-1)m,$$

as claimed. If  $m \geq 2k+1$ , then clause (ii) of Theorem 12 implies that  $e(H)$  is at most

$$\max \left\{ (k-1)m - ((k-1)^2 + (k-1))/2 + 1, \binom{2k-1}{2} + (m-2k-1) \right\}.$$

This bound splits into

$$e(H) \leq (k-1)m - ((k-1)^2 + (k-1))/2 + 1 \leq (k-1)m,$$

and

$$e(H) \leq \binom{2k-1}{2} + (m-2k+1) = (2k-1)(k-2) + m \leq (k-1)m.$$

Thus, in all cases we see that  $e(H) \leq (k-1)m$ , completing the proof of Lemma 5.  $\square$

PROOF OF LEMMA 6. Assume for a contradiction that

$$2e(G) - d_v \geq (2k-1)(n-1) + 1,$$

and that  $G$  has no path of order  $2k+1$  with both endvertices different from  $v$ . Write  $H$  for the component containing  $v$  and let  $F$  be the union of the other components of  $G$ . Since  $P_{2k+1} \not\subseteq F$ , Theorem 10 implies that

$$(2) \quad 2e(F) \leq (2k-1)v(F),$$

and so

$$2e(H) - d_v \geq (2k-1)(v(H)-1) + 1.$$

Noting that

$$2e(H) - d_v = \sum_{u \in V(H) \setminus \{v\}} d_u \leq (v(H)-1)^2,$$

we find that  $v(H) \geq 2k+1$ . Assume that  $v(H) \geq 2k+2$ . Since

$$2e(H) \geq (2k-1)(v(H)-1) + 1 + d_v > (2k-1)(v(H)-1),$$

Theorem 11 implies that  $H$  contains a cycle  $C$  of order  $m \geq 2k$ . If  $m \geq 2k+1$ , then obviously there is a  $P_{2k+1}$  with both endvertices different from  $v$ , so let  $m = 2k$ . Choose a vertex  $w \in V(H)$  such that  $w \neq v$  and  $w \notin C$ . There exists a shortest path  $P$  joining  $w$  to a vertex  $u \in C$ . By symmetry, we can index the vertices of  $C$

as  $u = u_1, u_2, \dots, u_{2k}$ . Take  $u_0$  in  $P$  at distance 1 from  $C$ . Then the sequences  $u_0, u_1, u_2, \dots, u_{2k}$  and  $u_0, u_1, u_{2k}, \dots, u_2$  induce paths of order  $2k + 1$ . Since  $v$  must be an endvertex to each of them, we see that  $u_0 = v$ . But  $w \neq v$ , hence  $P$  contains a vertex  $u_{-1}$  at distance 2 from  $C$ . Now the sequence  $u_{-1}, u_0, u_1, u_2, \dots, u_{2k-1}$  induces a path of order  $2k + 1$  with both endvertices different from  $v$ , a contradiction completing the proof whenever  $v(H) \geq 2k + 2$ . It remains to consider the case  $v(H) = 2k + 1$ . In this case  $H$  is not Hamiltonian, as otherwise there is a path of order  $2k + 1$  with both endvertices different from  $v$ ; hence, Theorem 13 implies that  $e(H) \leq k(2k - 1) + 1$  and so

$$2k(2k - 1) + 2 - d_v \geq e(H) - d_v \geq (2k - 1)2k + 1.$$

This is possible only if  $d_u = 1$  and  $e(H) = k(2k - 1) + 1$ . Since  $H - v$  is complete, obviously,  $H = K_{2k} + v$ . In addition, in (2) we have  $2e(F) = (2k - 1)v(F)$ , and so the condition for equality in Theorem 10 implies that  $G$  is a union of several copies of  $K_{2k}$  and one copy of  $K_{2k} + v$ , completing the proof of Lemma 6.  $\square$

PROOF OF LEMMA 7. Let  $q := q(G)$ ; assume for a contradiction that  $q \geq n + 2k - 2$ , and let  $\mathbf{x} = (x_1, \dots, x_n)$  be a unit eigenvector to  $q$ . From the eigenequation for  $Q(G)$  and the vertex  $w$  we see that

$$(q - n + 1)x_w \leq (q - d_w)x_w \leq \sum_{i \in V(G) \setminus \{w\}} x_i \leq \sqrt{(n - 1)(1 - x_w^2)},$$

and in view of  $q \geq n + 2k - 2$ , it follows that

$$(3) \quad x_w^2 \leq \frac{n - 1}{(q - n + 1)^2 + n - 1} < \frac{n - 1}{n - 1 + (2k - 1)^2} \leq 1 - \frac{9}{n + 8}.$$

On the other hand, let  $u \in V(F)$  be such that  $x_u = \max\{x_v : v \in V(F)\}$ . Set  $x := x_u$  and note that the eigenequation for  $u$  implies that

$$\begin{aligned} qx &= d_u x + \sum_{i \sim u} x_i = d_u x + x_w + \sum_{\{i, u\} \in E(F)} x_i \\ &\leq 2kx + x_w + (2k - 1)x = (4k - 1)x + x_w. \end{aligned}$$

Hence, the inequality  $q \geq n + 2k - 2$  implies that  $x \leq \frac{x_w}{q - 4k - 1} \leq \frac{x_w}{n - 2k - 1}$ . Next, expanding the quadratic form  $\langle Q(G)\mathbf{x}, \mathbf{x} \rangle$ , we find that

$$\begin{aligned} q &= \sum_{\{i, j\} \in E(G)} (x_i + x_j)^2 \leq \sum_{\{i, j\} \in E(G_0)} (x_i + x_j)^2 + 2kp(x + x_w)^2 + 4p \binom{2k}{2} x^2 \\ &\leq q(G_0) + 2kp(x + x_w)^2 + 4pk(2k - 1)x^2 \\ &= q(G_0) + 2pkx_w^2 + 4pkxx_w + 2pk(4k - 1)x^2 \\ &\leq q(G_0) + 2pk \left( 1 + \frac{2}{n - 2k - 1} + \frac{4k - 1}{(n - 2k - 1)^2} \right) x_w^2. \end{aligned}$$

Now, plugging here the bound (3), we get

$$(4) \quad q \leq q(G_0) + 2pk \left( 1 + \frac{3}{n - 2k - 1} \right) \left( 1 - \frac{9}{n + 8} \right)$$

$$\begin{aligned} &\leq q(G_0) + 2pk + 6pk \left( \frac{1}{n-2k-1} - \frac{3}{n+8} \right) \\ &= q(G_0) + 2pk - 6pk \left( \frac{2n-6k-13}{(n-2k-1)(n+8)} \right). \end{aligned}$$

Note that, in view of  $n \geq 6k + 13$  and  $k \geq 2$ , we have

$$\frac{2n-6k-13}{(n-2k-1)(n+8)} \geq \frac{n}{(n-2k-1)(n+8)} \geq \frac{n}{(n-5)(n+8)} > \frac{1}{n+3}.$$

Plugging this inequality back in (4) and using (1), we obtain

$$\begin{aligned} n + 2k - 2 \leq q &\leq q(G_0) + 2pk - \frac{6pk}{n+3} \\ &\leq m + 2k - 2 + \frac{6pk}{n+3} + 2pk - \frac{6pk}{n+3} = n + 2k - 2. \end{aligned}$$

Hence  $q \leq n + 2k - 2$ , with equality holding if and only if equality holds in (1). The proof of Lemma 7 is completed.  $\square$

PROOF OF COROLLARY 8. We shall apply Lemma 7 with  $H = K_{2k+2}$  and  $F = pK_{2k}$ . Clearly  $2pk = n - 2k - 2$  and so

$$\begin{aligned} q(H) = q(K_{2k+2}) &= 4k + 2 < v(H) + 2k - 2 + \frac{3(n-2k-2)}{n+3} \\ &= v(H) + 2k - 2 + \frac{6kp}{n+3}. \end{aligned}$$

In the derivation above we use that the inequality  $n \geq 6k + 13$  implies that  $3n - 6k - 6 > 2(n + 3)$ . The conditions for Lemma 7 are met and so  $q(G) < n + 2k - 2$ , completing the proof of Corollary 8.  $\square$

PROOF OF COROLLARY 9. Let  $F$  be the union of all components of  $G - w$  having order exactly  $2k$ , and let  $p$  be their number, possibly zero. Let  $H$  be the graph induced by the vertices in  $V(G) \setminus V(F)$ . Note that the hypothesis of Corollary 9 implies that  $e(H - w) \leq (k - 1)(m - 1)$  and so

$$e(H) \leq e(H - w) + m - 1 \leq (k - 1)(m - 1) + m - 1 = k(m - 1).$$

Now, from Theorem 16 we get

$$\begin{aligned} (5) \quad q(H) &\leq \frac{2e(H)}{m-1} + m - 2 \leq \frac{2k(m-1)}{m-1} + m - 2 \\ &= v(H) + 2k - 2 \leq v(H) + 2k - 2 + \frac{6kp}{n+3}. \end{aligned}$$

Since  $n \geq 6k + 13$ , we can apply Lemma 7, obtaining

$$q(G) < n + 2k - 2,$$

unless equality holds in (5). Equality in (5) implies that  $p = 0$ , that is to say  $G = H$ . Also, by the condition for equality in Theorem 16, we see that  $G$  is either complete, or is a star, or is a complete graph with one isolated vertex. Since  $q(G) = n + 2k - 2$ ,  $G$  cannot be a star. If  $G$  is complete, then  $n + 2k - 2 = 2n - 2$  and

so  $n = 2k$ , contradicting that  $n \geq 6k + 13$ . For the same reason  $n + 2k - 2 < 2n - 4$  and so  $G$  cannot be a complete graph with one isolated vertex either. Corollary 9 is proved.  $\square$

PROOF OF THEOREM 3. For short, set  $q := q(G)$  and  $V := V(G)$ . Assume for a contradiction that  $G$  is a graph of order  $n > 6k^2$ , with  $q \geq n + 2k - 2$ , and suppose that  $C_{2k+1} \not\subseteq G$  or  $C_{2k+2} \not\subseteq G$ . We may and shall suppose that  $G$  is edge maximal, because edge addition does not decrease the  $Q$ -index. In particular, this assumption implies that  $G$  is connected.

Let  $w$  be a vertex for which the expression

$$d_w + \frac{1}{d_w} \sum_{i \sim w} d_i$$

is maximal. We shall show that

$$(6) \quad d_w + \frac{1}{d_w} \sum_{i \sim w} d_i \leq n + 2k - 2.$$

This is enough to prove Theorem 3, unless

$$q = d_w + \frac{1}{d_w} \sum_{i \sim w} d_i.$$

However,  $G$  is connected, so if equality holds in (6) Theorem 15 implies that  $G$  is regular or bipartite semiregular; it is not hard to see that neither of these conditions can hold. Indeed, if  $G$  is bipartite, then  $q \leq n$ . If  $G$  is regular, then  $q = 2\delta \leq n$ , as otherwise, Bondy's theorem [2] implies that  $G$  is pancyclic. So to the end of the proof we shall focus on the proof of (6).

For short, set  $A = \Gamma_w$ ,  $B = V(G) \setminus (\Gamma_w \cup \{w\})$ , and  $G_w = G[V \setminus \{w\}]$ . Obviously,  $|A| = d_w$  and  $|A| + |B| = n - 1$ . First we shall prove that  $C_{2k+1} \subset G$ . Assume thus that  $C_{2k+1} \not\subseteq G$ ; clearly  $P_{2k} \not\subseteq G[A]$ , and so Theorem 10 implies that  $e(A) \leq (k - 1)|A|$ . Now

$$\begin{aligned} d_w + \frac{1}{d_w} \sum_{i \sim w} d_i &= |A| + 1 + \frac{2e(A) + e(A, B)}{|A|} \leq |A| + 1 + \frac{2(k - 1)|A| + |A||B|}{|A|} \\ &\leq |A| + 1 + 2k - 2 + |B| = n + 2k - 2. \end{aligned}$$

This completes the proof that  $C_{2k+1} \subset G$ . The proof that  $C_{2k+2} \subset G$  is somewhat longer. Assume that  $C_{2k+2} \not\subseteq G$  and note that if  $d_w \leq 2k - 1$ , then

$$d_w + \frac{1}{d_w} \sum_{i \sim w} d_i = d_w + \Delta \leq 2k - 1 + n - 1 = n + 2k - 2,$$

so (6) holds. Thus, hereafter we shall assume that  $d_w \geq 2k$ . Further, note that the graph  $G_w$  contains no path with both endvertices in  $A$ , as otherwise  $C_{2k+2} \subset G$ . Hence, Theorem 14 implies that

$$2e(A) + e(A, B) \leq (2k - 1)|A| + k|B| = (k - 1)d_w + k(n - 1),$$

and therefore

$$\begin{aligned} d_w + \frac{1}{d_w} \sum_{i \sim w} d_i &= d_w + 1 + \frac{2e(A) + e(A, B)}{d_w} \\ &\leq d_w + 1 + \frac{(k-1)d_w + k(n-1)}{d_w} = d_w + k + \frac{k(n-1)}{d_w}. \end{aligned}$$

The function  $x + k(n-1)/x$  is convex for  $x > 0$ ; hence, the maximum of the expression  $d_w + k(n-1)/d_w$  is attained for the minimum and maximum admissible values for  $d_w$ . Since  $d_w \geq 2k$ , in either case we find that

$$d_w + \frac{1}{d_w} \sum_{i \sim w} d_i < n + 2k - 2,$$

unless  $d_w \geq n - 2$ . Therefore, to complete the proof we only need to consider the cases  $d_w = n - 2$  and  $d_w = n - 1$ . First, suppose that  $d_w = n - 2$  and let  $v$  be the vertex of  $G$  such that  $v \neq w$  and  $v \notin \Gamma_w$ . Note that  $G_w$  contains no path of order  $2k + 1$  with both endvertices different from  $v$ , as such a path would make a  $C_{2k+2}$  with  $w$ . Therefore, the hypothesis of Lemma 6 is satisfied, and so either

$$(7) \quad 2e(A) + e(A, B) = 2e(G_w) - d_v \leq (2k - 1)(n - 2)$$

or  $G_w$  is a union of several copies of  $K_{2k}$  and one  $K_{2k} + v$ . If (7) holds, we see that

$$\begin{aligned} d_w + \frac{1}{d_w} \sum_{i \sim w} d_i &\leq n - 2 + 1 + \frac{2e(A) + e(A, B)}{n - 2} \\ &\leq n - 1 + \frac{(2k - 1)(n - 2)}{(n - 2)} = n + 2k - 2, \end{aligned}$$

completing the proof of (6). On the other hand, if  $G_w$  is a union of several copies of  $K_{2k}$  and one  $K_{2k} + v$ , then  $G$  is a spanning subgraph of the graph  $G' = K_1 \vee ((pK_{2k}) \cup K_{2k+1})$ , with  $p$  chosen so that  $n = 2(p + 1)k + 2$ . Since  $n \geq 6k^2 + 1 \geq 6k + 13$ , we can apply Corollary 8 obtaining that

$$q(G) < q(G') < n + 2k - 2,$$

which contradicts the assumption and completes the proof of Theorem 3 if  $d_w = n - 2$ .

Finally, let  $d_w = n - 1$ . Since  $G_w$  contains no  $P_{2k+1}$ , Lemma 5 implies that for each component  $C$  of  $G_w$ , either  $v(C) = 2k$  or  $e(C) \leq (k - 1)v(C)$ . Since  $n \geq 6k^2 + 1 \geq 6k + 13$ , the graph  $G$  satisfies the hypothesis of Corollary 9, and so

$$q(G) < n + 2k - 2,$$

completing the proof of Theorem 3.  $\square$
