

Embedding dimension of the Dirichlet space

Michael Hartz

ABSTRACT. The classical Dirichlet space is a complete Pick space, hence by a theorem of Agler and M^cCarthy, there exists an embedding b of the unit disc into a d -dimensional ball such that composition with b realizes the Dirichlet space as a quotient of the Drury–Arveson space. We show that $d = \infty$ is necessary, even if we only demand that composition with b induces a surjective map between the multiplier algebras.

1. Introduction

1.1. Background. The classical Dirichlet space on the open unit disc $\mathbb{D} \subset \mathbb{C}$ is defined as

$$\mathcal{D} = \left\{ f \in \mathcal{O}(\mathbb{D}) : \int_{\mathbb{D}} |f'|^2 dA < \infty \right\},$$

where dA denotes the normalized area measure on \mathbb{D} . Equipped with the norm

$$\|f\|^2 = \int_{\mathbb{D}} |f'|^2 dA + \|f\|_{H^2}^2,$$

where H^2 denotes the classical Hardy space and

$$\|f\|_{H^2}^2 = \sup_{0 \leq r < 1} \int_0^{2\pi} |f(re^{it})|^2 \frac{dt}{2\pi},$$

Key words and phrases. Dirichlet space, complete Pick space, Drury–Arveson space, pseudo-hyperbolic metric.

The author was partially supported by a GIF grant.

the Dirichlet space is a reproducing kernel Hilbert space of functions on \mathbb{D} with reproducing kernel

$$k(z, w) = \frac{1}{zw} \log \left(\frac{1}{1 - z\bar{w}} \right).$$

For background and motivation, the reader is referred to the books [12, 5].

An important feature of the Dirichlet space is the complete Pick property, meaning that \mathcal{D} satisfies a version of the classical Pick interpolation theorem; see [2] for background. This key realization, due to Agler, has led to the solution of some open problems in the Dirichlet space, such as the characterization of interpolating sequences due to Marshall and Sundberg [19] (a different proof was given independently by Bishop [7]), quotient representations of functions in \mathcal{D} by Aleman, M^cCarthy, Richter and the author [3], and factorization in the weak product space by Jury and Martin [15].

A theorem of Agler and M^cCarthy [1] shows that the complete Pick property of \mathcal{D} is equivalent to the existence of a number $d \in \mathbb{N} \cup \{\infty\}$ and a map $b : \mathbb{D} \rightarrow \mathbb{B}_d$, so that

$$k(z, w) = \frac{1}{1 - \langle b(z), b(w) \rangle} \quad (z, w \in \mathbb{D}). \tag{1}$$

Here, \mathbb{B}_d is the open unit ball in \mathbb{C}^d , which is understood as ℓ^2 if $d = \infty$. (In general, one needs to allow rescalings of the form $\frac{\delta(z)\bar{\delta(w)}}{1 - \langle b(z), b(w) \rangle}$ for a nowhere vanishing function δ , but one can achieve that $\delta = 1$ since $k(z, 0) = 1$ for all z .) In fact, the complete Pick property of \mathcal{D} is often applied by using that (1) holds, as in the works [3, 15] mentioned above. We will explicitly construct such a map b in Section 5.

The relation (1) can be interpreted in the following way. Let $K(z, w) = \frac{1}{1 - \langle z, w \rangle}$ for $z, w \in \mathbb{B}_d$. This is a positive definite kernel, and the corresponding reproducing kernel Hilbert space is denoted by H_d^2 and called the Drury–Arveson space [6]. The theorem of Agler and M^cCarthy can be interpreted as saying that H_d^2 is a universal complete Pick space. In particular, in the case of the Dirichlet space, (1) can be rephrased by saying that b induces a co-isometric composition operator

$$H_d^2 \rightarrow \mathcal{D}, \quad f \mapsto f \circ b;$$

see Proposition 4.1 for more details. As a consequence, on the level of multiplier algebras, b induces a (complete) quotient mapping

$$\Phi : \text{Mult}(H_d^2) \rightarrow \text{Mult}(\mathcal{D}), \quad \varphi \mapsto \varphi \circ b,$$

meaning that the induced map $\text{Mult}(H_d^2) / \ker(\Phi) \rightarrow \text{Mult}(\mathcal{D})$ is a (completely) isometric isomorphism. In particular, Φ is surjective. These implications will also be reviewed in Proposition 4.1.

It turns out that H_d^2 and its multiplier algebra are significantly more tractable if $d < \infty$. To give a concrete example, the maximal ideal space $\mathcal{M}(\text{Mult}(H_d^2))$

of $\text{Mult}(H_d^2)$ is fibered over $\overline{\mathbb{B}_d}$ via the map

$$\pi : \mathcal{M}(\text{Mult}(H_d^2)) \rightarrow \overline{\mathbb{B}_d}, \quad \chi \mapsto (\chi(z_1), \chi(z_2), \dots).$$

If $d < \infty$, the fibers over the open ball \mathbb{B}_d are singletons. But if $d = \infty$, the fibers are extremely complicated. Indeed, $\pi^{-1}(0)$ contains a copy of the Stone-Ćech remainder $\beta\mathbb{N} \setminus \mathbb{N}$ if $d = \infty$. This has led to some issues in the area; cf. [10].

1.2. Main result. Since H_d^2 is more tractable if $d < \infty$, the question arose for which complete Pick spaces one can achieve $d < \infty$ in the Agler–McCarthy theorem. In particular, it was asked whether this is possible for the Dirichlet space, see [23, Section 7.5]. It was shown independently by Rochberg [21] and by the author [13, Corollary 11.9] that an embedding $b : \mathbb{D} \rightarrow \mathbb{B}_d$ for which relation (1) holds only exists if $d = \infty$. However, for a number of questions, a weaker relation than (1) would be sufficient. For instance, one might only demand that b induces a surjective composition operator $H_d^2 \rightarrow \mathcal{D}$. Perhaps one of the weakest reasonable notions of embedding is to demand that b induces a surjective map $\text{Mult}(H_d^2) \rightarrow \text{Mult}(\mathcal{D})$, which is still sufficient for understanding algebraic properties of $\text{Mult}(\mathcal{D})$, such as the maximal ideal space. The relationship between this and other notions of embedding will be explained in Proposition 4.1.

The main result of this note shows that even with this weak notion of embedding, $d = \infty$ is necessary. In particular, this answers the question raised by Salomon and Shalit in [23, Section 7.5]. For a statement adapted to the setting of [23], see also Theorem 4.2.

Theorem 1.1. *There does not exist a map $b : \mathbb{D} \rightarrow \mathbb{B}_d$ with $d \in \mathbb{N}$ that induces a surjective homomorphism*

$$\text{Mult}(H_d^2) \rightarrow \text{Mult}(\mathcal{D}), \quad \varphi \mapsto \varphi \circ b.$$

This result will be proved in Section 3. The arguments involving ranks of kernels, which were used in [13] to show that (1) cannot hold for $d < \infty$, do not seem to generalize to the setting of Theorem 1.1. Instead, we will refine Rochberg’s geometric arguments of [21]. He observed that if (1) holds, then b is an isometric embedding from the disc, equipped with a suitable metric related to the Dirichlet space, into the ball, equipped with the pseudohyperbolic metric. He then used geometric arguments to show that this is impossible for $d < \infty$.

The proof of Theorem 1.1 follows a similar outline. First, we will show that if $b : \mathbb{D} \rightarrow \mathbb{B}_d$ induces a surjective homomorphism as in Theorem 1.1, then b has to be a bi-Lipschitz embedding with respect to the metrics mentioned above. We will then identify geometric obstructions showing that this is impossible if $d < \infty$. The basic idea of the geometric argument is similar to that in Rochberg’s proof, but the bi-Lipschitz setting necessitates significant changes compared to the isometric setting.

1.3. An explicit embedding into \mathbb{B}_∞ . In Section 5, we will explicitly construct a map $b : \mathbb{D} \rightarrow \mathbb{B}_\infty$ such that the reproducing kernel k of the Dirichlet space has the representation

$$k(z, w) = \frac{1}{1 - \langle b(z), b(w) \rangle} \quad (z, w \in \mathbb{D}).$$

As is well known, the key point in proving the existence of an embedding is to show that the real numbers $(c_n)_{n=1}^\infty$ defined by the power series identity

$$\sum_{n=1}^{\infty} c_n (z\bar{w})^n = 1 - \frac{1}{k(z, w)} \quad (2)$$

satisfy $c_n \geq 0$ for all $n \geq 1$. In this case, considering (2) on the diagonal $z = w$, we find that $\sum_{n=1}^{\infty} c_n \leq 1$, so defining

$$b : \mathbb{D} \rightarrow \mathbb{B}_\infty, \quad b(z) = (\sqrt{c_1}z, \sqrt{c_2}z^2, \sqrt{c_3}z^3, \dots),$$

we obtain the desired embedding.

In the literature on complete Pick spaces, the usual proof of the fact that the numbers c_n in (2) are non-negative makes use of a lemma of Kaluza; see [19] or [2, Corollary 7.41]. While the coefficients c_n can be obtained from the Taylor coefficients of k through a recursive formula, this does not give an explicit formula for c_n . In the discussion following Corollary 11 in [19], Marshall and Sundberg ask if it is possible to see directly from the formula for the kernel k that $c_n \geq 0$ for all $n \geq 1$.

We show that an argument from the work of Kluyver [17] yields an explicit formula for c_n , which shows in particular that $c_n \geq 0$ for all $n \geq 1$.

Proposition 1.2. *For $n \geq 1$, we have*

$$c_n = \int_0^1 t \frac{\Gamma(n-t)}{\Gamma(n+1)\Gamma(1-t)} dt \geq 0.$$

This result will be proved in Section 5.

1.4. Reader's guide. The remainder of this note is organized as follows. In Section 2, we recall some necessary preliminaries for the proof of the main result, which occupies Section 3. In Section 4, we show that Theorem 1.1 also rules out the existence of some other types of embedding for the Dirichlet space. Finally, in Section 5, we prove Proposition 1.2.

Remark. A draft version of this note was circulated in 2016. Since the draft has been cited a few times, the author decided to make this note more widely available.

2. Preliminaries about metrics

In this section, we collect the necessary background on metrics induced by reproducing kernels. More information on this topic can be found in [4] and [2, Chapter 9].

2.1. Metrics induced by kernels. Suppose \mathcal{H} is a reproducing kernel Hilbert space of functions on a set X with reproducing kernel K . Throughout, we will assume that $K(z, z) \neq 0$ for all $z \in X$. We say that \mathcal{H} *separates the points of X* if whenever $z, w \in X$ with $z \neq w$, there exists $f \in \mathcal{H}$ with $f(z) = 0$ and $f(w) = 1$. This is equivalent to saying that $K(\cdot, z)$ and $K(\cdot, w)$ are linearly independent whenever $z \neq w$.

We can define a pseudo-metric $\delta_{\mathcal{H}}$ on X by

$$\delta_{\mathcal{H}}(z, w) = \left(1 - \frac{|K(z, w)|^2}{K(z, z)K(w, w)}\right)^{1/2}. \quad (3)$$

This is a metric if \mathcal{H} separates the points of X , see [2, Lemma 9.9] or [4, Section 4].

If $\mathcal{H} = H^2$, the Hardy space on the disc, then a computation with Szegő kernels shows that

$$\delta_{H^2}(z, w) = \left| \frac{z - w}{1 - \bar{z}w} \right| \quad (z, w \in \mathbb{D}),$$

so δ_{H^2} is the pseudohyperbolic metric on \mathbb{D} ; see [4, Section 2].

More generally, the metric $\delta_{H_d^2}$ associated with the Drury–Arveson space turns out to be the pseudohyperbolic metric on \mathbb{B}_d for $d \in \mathbb{N}$. Background information on the pseudohyperbolic metric on the ball can be found in [11]. To recall, we have for each $a \in \mathbb{B}_d$ the biholomorphic automorphism

$$\varphi_a : \mathbb{B}_d \rightarrow \mathbb{B}_d, \quad \varphi_a(z) = \frac{a - P_a(z) - s_a Q_a(z)}{1 - \langle z, a \rangle},$$

where P_a is the orthogonal projection onto $\mathbb{C}a$, $Q_a = I - P_a$ and $s_a = (1 - \|a\|^2)^{1/2}$; see [22, Section 2.2]. The identity

$$1 - \|\varphi_w(z)\|^2 = \frac{(1 - \|w\|^2)(1 - \|z\|^2)}{|1 - \langle z, w \rangle|^2}$$

(see [22, Theorem 2.2.2 (iv)]) shows that

$$\delta_{H_d^2}(z, w) = \|\varphi_w(z)\|,$$

which by definition is the pseudohyperbolic distance between z and w , usually denoted by $\rho(z, w)$.

In the case of the Dirichlet space, we obtain the formula

$$\delta_{\mathcal{D}}(z, w) = \left(1 - \frac{|\log(1 - \bar{z}w)|^2}{\log(1 - |z|^2)\log(1 - |w|^2)}\right)^{1/2} \quad (4)$$

for $z, w \in \mathbb{D} \setminus \{0\}$.

2.2. Length of curves. The metrics $\delta_{\mathcal{H}}$ defined in (3) will not be quite sufficient in our setting. In addition, we will make use of length metrics induced by the metrics $\delta_{\mathcal{H}}$. Background on this topic can be found in [4] and [20], see also [14].

If (X, d) is a metric space and $\gamma : [a, b] \rightarrow X$ is a (continuous) curve, the *length* of γ with respect to d is defined by

$$\ell_d(\gamma) = \sup \left\{ \sum_{j=0}^{n-1} d(\gamma(t_j), \gamma(t_{j+1})) : a = t_0 < t_1 < \dots < t_n = b \right\}.$$

We also set

$$d^*(z, w) = \inf\{\ell_d(\gamma) : \gamma \text{ is a curve joining } z \text{ to } w\}.$$

It is well known that if ρ is the pseudo-hyperbolic metric on \mathbb{B}_d , then ρ^* is the Poincaré–Bergman metric

$$\beta(z, w) = \tanh^{-1} \rho(z, w) = \frac{1}{2} \log \left(\frac{1 + \rho(z, w)}{1 - \rho(z, w)} \right).$$

We will indicate below how to see this fact in the present framework of metrics induced by kernels; see also [14, Chaper 1] for a direct proof in the case $d = 1$.

Mazur, Pflug and Skwarzcyński [20] showed that if the metric d is derived from the Bergman kernel of a domain in \mathbb{C}^d in a manner similar to (3), then the associated metric d^* is essentially the Bergman metric of the domain, which is a Riemannian metric that can be explicitly computed from the Bergman kernel; see for instance [18, Section 1.4] for background on the Bergman metric. Arcozzi, Rochberg, Sawyer and Wick [4] observed that the results of [20] extend to much more general spaces of holomorphic functions. We will make use of these results in the case of the Dirichlet space and of the Drury–Arveson space.

Lemma 2.1.

(a) *For the pseudohyperbolic metric ρ on \mathbb{B}_d , the metric ρ^* coincides with the Poincaré–Bergman metric β .*

(b) *Let $\gamma : [a, b] \rightarrow \mathbb{D}$ be a piecewise C^1 curve. Then the length of γ with respect to the Dirichlet space metric $\delta_{\mathcal{D}}$ is given by*

$$\ell_{\delta_{\mathcal{D}}}(\gamma) = \int_a^b g(\gamma(t))^{1/2} |\gamma'(t)| dt,$$

where $g : \mathbb{D} \rightarrow [0, \infty)$ is the continuous function given by

$$g(z) = \frac{\log\left(\frac{1}{1-|z|^2}\right) - |z|^2}{\left(\log\left(\frac{1}{1-|z|^2}\right)\right)^2 (1 - |z|^2)^2} \quad (z \neq 0)$$

and $g(0) = \frac{1}{2}$.

Proof. It was shown in [20, Theorem 1] that if K is the square root of the kernel of the Bergman space on a bounded domain D in \mathbb{C}^d and if $\delta_{\mathcal{H}}$ is defined as in

(3), then the length of any piecewise C^1 curve $\gamma : [a, b] \rightarrow D$ is given by

$$\ell_{\delta_{\mathcal{H}}}(\gamma) = \int_a^b \left(\sum_{j,k=1}^d \frac{\partial^2 \log K(\gamma(t), \gamma(t))}{\partial \bar{z}_j \partial z_k} \overline{\gamma'_j(t) \gamma'_k(t)} \right)^{1/2} dt. \quad (5)$$

(The result in [20] involves additional factors of $\frac{1}{2}$ and $\sqrt{2}$ because they consider the square root of the reproducing kernel.) It was observed in [4, Proposition 9] that this formula, which is proved by second order Taylor approximations to the kernel functions, holds much more generally, and in particular in the case of the Drury–Arveson space and of the Dirichlet space.

(a) Applying (5) to the Drury–Arveson kernel K and recalling that the ordinary Bergman kernel on \mathbb{B}_d is given by K^{d+1} , it follows from standard results about the Poincaré–Bergman metric (see, for example, [26, Proposition 1.21]) that

$$\beta(z, w) = \inf\{\ell_{\rho}(\gamma) : \gamma \text{ is a piecewise smooth curve in } \mathbb{B}_d \text{ joining } z \text{ and } w\}.$$

Moreover, [20, Theorem 2] (see also [4, Proposition 9]) shows that the right-hand side remains unchanged when taking the infimum over all continuous curves, hence $\beta = \rho^*$.

(b) We apply (5) to the Dirichlet kernel k . A simple computation shows that for $z \neq 0$, we have

$$\frac{\partial^2 \log k(z, z)}{\partial z \partial \bar{z}} = \frac{\partial^2}{\partial z \partial \bar{z}} \log \log \left(\frac{1}{1 - |z|^2} \right) = g(z).$$

Direct inspection of the Taylor series of $\log(1 - z)$ at the origin shows that g extends continuously to 0 with $g(0) = \frac{1}{2}$, so the above identity holds for all $z \in \mathbb{D}$, and the statement follows from (5). \square

Remark 2.2. In Lemma 2.1 (a), we will actually only need the lower bound $\beta \leq \rho^*$. This lower bound can be proved in a more elementary way as follows. Since $\rho = \tanh(\beta)$ and since the derivative of \tanh at 0 equals 1, a simple estimate shows that $\ell_{\rho}(\gamma) = \ell_{\beta}(\gamma)$ for any continuous curve γ , see [14, Lemma 2.5.2 (a)]. So if γ is a continuous curve joining z and w , then $\beta(z, w) \leq \ell_{\beta}(\gamma) = \ell_{\rho}(\gamma)$, which gives the inequality $\beta \leq \rho^*$.

3. Proof of main result

3.1. From surjective homomorphisms to bi-Lipschitz embeddings. In the first step towards the proof of Theorem 1.1, we show that any surjective homomorphism as in Theorem 1.1 induces a bi-Lipschitz embedding of $(\mathbb{D}, \delta_{\mathcal{D}})$ into $(\mathbb{B}_d, \delta_{H^2_d})$. We need the following characterization of the metric $\delta_{\mathcal{H}}$ in terms of the multiplier algebra for complete Pick spaces. It applies in particular to the Dirichlet space and to the Drury–Arveson space.

Lemma 3.1. *Let \mathcal{H} be a complete Pick space on X . Then*

$$\delta_{\mathcal{H}}(z, w) = \sup\{|\varphi(z)| : \varphi(w) = 0, \|\varphi\|_{\text{Mult}(\mathcal{H})} \leq 1\}$$

for all $z, w \in X$. Moreover, the supremum is attained.

Proof. The result is well known. For the convenience of the reader, we provide a short argument. Let $z, w \in X$ and let $\lambda \in \mathbb{C}$. By the Pick property, there exists $\varphi \in \text{Mult}(\mathcal{H})$ with $\|\varphi\|_{\text{Mult}(\mathcal{H})} \leq 1$, $\varphi(w) = 0$ and $\varphi(z) = \lambda$ if and only if the Pick matrix

$$\begin{bmatrix} K(z, z)(1 - |\lambda|^2) & K(z, w) \\ K(w, z) & K(w, w) \end{bmatrix}$$

is positive semi-definite. By Sylvester's criterion, this happens if and only if $|\lambda| \leq 1$ and the determinant of the matrix is non-negative, which after rearranging is seen to be equivalent to

$$|\lambda| \leq \left(1 - \frac{|K(z, w)|^2}{K(z, z)K(w, w)}\right)^{1/2}.$$

Since the right-hand side equals $\delta_{\mathcal{H}}(z, w)$, the result follows. \square

If E is a Banach space, we denote the closed unit ball of E by B_E . If $T : E \rightarrow F$ is a surjective continuous linear operator between Banach spaces, let

$$q(T) = \sup\{r \geq 0 : T(B_E) \supset rB_F\}$$

be the surjectivity modulus of T . By the open mapping theorem, $q(T) > 0$. If $\tilde{T} : E/\ker(T) \rightarrow F$ denotes the induced operator, then $q(T) = \|\tilde{T}^{-1}\|^{-1}$.

The following result generalizes [9, Theorem 6.2]. The Lipschitz constant obtained below is an improvement of the Lipschitz constant obtained there by a factor of 2.

Proposition 3.2. *Let \mathcal{H} and \mathcal{K} be complete Pick spaces on X and Y , respectively. Let $F : Y \rightarrow X$ be a mapping that induces a homomorphism*

$$\Phi : \text{Mult}(\mathcal{H}) \rightarrow \text{Mult}(\mathcal{K}), \quad \varphi \mapsto \varphi \circ F.$$

(a) *The homomorphism Φ is continuous, and F is Lipschitz with*

$$\delta_{\mathcal{H}}(F(z), F(w)) \leq \|\Phi\| \delta_{\mathcal{K}}(z, w) \quad \text{for all } z, w \in Y.$$

(b) *If Φ is surjective, then $q(\Phi) > 0$ and F is bi-Lipschitz with*

$$q(\Phi) \delta_{\mathcal{K}}(z, w) \leq \delta_{\mathcal{H}}(F(z), F(w)) \leq \|\Phi\| \delta_{\mathcal{K}}(z, w) \quad \text{for all } z, w \in Y.$$

Proof. (a) Since multiplier algebras are commutative semi-simple Banach algebras, the homomorphism Φ is continuous by a standard automatic continuity result; see, for instance, [16, Corollary 2.1.10]. Let $C > \|\Phi\|$ and let $z, w \in Y$. By Lemma 3.1, there exists $\varphi \in \text{Mult}(\mathcal{H})$ of norm at most 1 such that $\varphi(F(z)) = 0$ and $\varphi(F(w)) = \delta_{\mathcal{H}}(F(z), F(w))$. Let $\psi = C^{-1}(\varphi \circ F)$. Then ψ belongs to the unit ball of $\text{Mult}(\mathcal{K})$ and $\psi(z) = 0$ and $\psi(w) = C^{-1} \delta_{\mathcal{H}}(F(z), F(w))$. Another application of Lemma 3.1 shows that

$$\delta_{\mathcal{K}}(z, w) \geq C^{-1} \delta_{\mathcal{H}}(F(z), F(w)).$$

Since $C > \|\Phi\|$ was arbitrary, the result follows.

(b) Suppose that Φ is surjective. By the open mapping theorem, $q(T) > 0$. Let $z, w \in Y$. By Lemma 3.1, there exists $\psi \in \text{Mult}(\mathcal{K})$ of norm at most 1 with

$\psi(z) = 0$ and $\psi(w) = \delta_{\mathcal{X}}(z, w)$. Let $0 < \varepsilon < q(T)$. By definition of $q(\Phi)$, there exists $\varphi \in \text{Mult}(\mathcal{H})$ of norm at most 1 such that $\varphi \circ F = \varepsilon\psi$. Then $\varphi(F(z)) = 0$ and $\varphi(F(w)) = \varepsilon\delta_{\mathcal{X}}(z, w)$, so Lemma 3.1 shows that

$$\delta_{\mathcal{H}}(F(z), F(w)) \geq \varepsilon\delta_{\mathcal{X}}(z, w).$$

Since $\varepsilon < q(T)$ was arbitrary, the first inequality follows. The second inequality was already established in (a). \square

The following consequence is immediate from part (b) of Proposition 3.2.

Corollary 3.3. *Let $d \in \mathbb{N}$. If $b : \mathbb{D} \rightarrow \mathbb{B}_d$ induces a surjective homomorphism*

$$\text{Mult}(H_d^2) \rightarrow \text{Mult}(\mathcal{D}), \quad \varphi \mapsto \varphi \circ b,$$

then b is a bi-Lipschitz map from $(\mathbb{D}, \delta_{\mathcal{D}})$ into $(\mathbb{B}_d, \delta_{H_d^2})$. \square

We will show that no such bi-Lipschitz map exists.

3.2. Lipschitz maps into the ball. In the sequel, we will simply write $\delta = \delta_{\mathcal{D}}$ for the metric on \mathbb{D} induced by the Dirichlet space. We also continue to write $\rho = \delta_{H_d^2}$ for the pseudo-hyperbolic metric on \mathbb{B}_d .

Our next goal is to show that if $f : (\mathbb{D}, \delta) \rightarrow (\mathbb{B}_d, \rho)$ is Lipschitz with $f(0) = 0$, then $\|f(z)\|$ can only approach 1 very slowly as $|z|$ approaches 1; that is, we seek upper bounds on $\|f(z)\|$. For isometric maps f , this was done by Rochberg [21] by noting that $\|f(z)\| = \rho(0, f(z)) = \delta(0, z)$ in this case and estimating $1 - \delta(0, z)$. In the bi-Lipschitz setting, the upper bound on $\|f(z)\|$ that can be deduced from this argument takes the form $\|f(z)\| \leq C\delta(0, z)$ for some constant C . This is not a very useful estimate if $|z|$ is close to 1, because we always have the trivial upper bound $\|f(z)\| \leq 1$. Instead, we will use lengths of curves as defined in Subsection 2.2 to obtain a better upper bound on $\|f(z)\|$.

If $f, g : [0, 1) \rightarrow [0, \infty)$ are two functions, we will write $f \sim g$ as $r \rightarrow 1$ if f and g do not vanish near 1 and $\lim_{r \rightarrow 1} \frac{f(r)}{g(r)} = 1$.

Lemma 3.4. *Let $0 \leq r < 1$ and let $\gamma_r : [0, r] \rightarrow \mathbb{D}, t \mapsto t$. Then*

$$\ell_{\delta}(\gamma_r) \sim \left(\log \left(\frac{1}{1-r} \right) \right)^{1/2} \quad \text{as } r \rightarrow 1.$$

Hence, there exists a constant $M \in (0, \infty)$ such that

$$\ell_{\delta}(\gamma_r) \leq M \left(\log \left(\frac{1}{1-r} \right) \right)^{1/2} \quad \text{for all } r \in [0, 1).$$

Proof. Let $g : \mathbb{D} \rightarrow [0, \infty)$ be the continuous function appearing in part (b) of Lemma 2.1. By that lemma, $\ell_{\delta}(\gamma_r) = \int_0^r g(t)^{1/2} dt$, hence

$$\frac{d\ell_{\delta}(\gamma_r)}{dr} = g(r)^{1/2} \sim \frac{1}{\left(\log \left(\frac{1}{1-r^2} \right) \right)^{1/2} (1-r^2)} \sim \frac{1}{2 \left(\log \left(\frac{1}{1-r} \right) \right)^{1/2} (1-r)}$$

as $r \rightarrow 1$. On the other hand,

$$\frac{d}{dr} \left(\log \left(\frac{1}{1-r} \right) \right)^{1/2} = \frac{1}{2 \left(\log \left(\frac{1}{1-r} \right) \right)^{1/2} (1-r)}.$$

The first statement now follows from L'Hôpital's rule.

To deduce the second statement from the first one, it suffices to show that the desired estimate holds for fixed $r_0 < 1$ and all $r \in [0, r_0]$. But if $r_0 < 1$, then g is bounded on $[0, r_0]$. So if $M > 0$ is such that $|g(t)|^{1/2} \leq M$ for all $t \in [0, r_0]$, then for all $r \in [0, r_0]$, we have

$$\ell_\delta(\gamma_r) \leq Mr \leq Mr^{1/2} \leq M \left(\log \left(\frac{1}{1-r} \right) \right)^{1/2}.$$

as desired. \square

The following proposition now shows that for any Lipschitz map $f : (\mathbb{D}, \delta) \rightarrow (\mathbb{B}_d, \rho)$ with $f(0) = 0$, the quantity $\|f(z)\|$ can only approach 1 very slowly as $|z| \rightarrow 1$.

Proposition 3.5. *Let $f : (\mathbb{D}, \delta) \rightarrow (\mathbb{B}_d, \rho)$ be a Lipschitz mapping with $f(0) = 0$. Then there exists a constant $C \in (0, \infty)$ such that*

$$\|f(z)\| \leq 1 - \exp \left(-C \left(\log \left(\frac{1}{1-|z|} \right) \right)^{1/2} \right) \quad \text{for all } z \in \mathbb{D}.$$

In particular, for any $\alpha > 0$, there exists $r_0 \in (0, 1)$ such that

$$\|f(z)\| \leq 1 - (1 - |z|)^\alpha$$

for all $z \in \mathbb{D}$ with $|z| \geq r_0$.

Proof. Since f is Lipschitz, there exists a constant $L \in (0, \infty)$ such that

$$\rho(f(z), f(w)) \leq L\delta(z, w)$$

for all $z, w \in \mathbb{D}$. It easily follows from the definition of the length of a curve that

$$\ell_\rho(f \circ \gamma) \leq L\ell_\delta(\gamma)$$

for every curve $\gamma : [a, b] \rightarrow \mathbb{D}$.

Now, let $z \in \mathbb{D}$, let $r = |z|$ and write $z = \lambda r$ for $\lambda \in \mathbb{C}$ with $|\lambda| = 1$. Let $\gamma_r : [0, r] \rightarrow \mathbb{D}, t \mapsto t$. Then $f \circ (\lambda \gamma_r)$ is a curve in \mathbb{B}_d from 0 to $f(z)$, hence Lemma 2.1 (a), see also Remark 2.2, and rotation invariance of the metric δ imply that

$$\beta(0, f(z)) = \rho^*(0, f(z)) \leq \ell_\rho(f \circ (\lambda \gamma_r)) \leq L\ell_\delta(\lambda \gamma_r) = L\ell_\delta(\gamma_r).$$

Estimating the right-hand side with the help of Lemma 3.4 and recalling the definition of β , we find that

$$\log \left(\frac{1}{1 - \|f(z)\|} \right) \leq 2\beta(0, f(z)) \leq 2LM \left(\log \left(\frac{1}{1-r} \right) \right)^{1/2}.$$

Rearranging this inequality gives the first statement with $C = 2LM$.

As for the second statement, let $\alpha > 0$ and choose $r_0 \in (0, 1)$ so that $C \leq \alpha(\log(\frac{1}{1-r_0}))^{1/2}$. If $|z| \geq r_0$, then the first estimate yields

$$\begin{aligned} \|f(z)\| &\leq 1 - \exp\left(-C\left(\log\left(\frac{1}{1-|z|}\right)\right)^{1/2}\right) \leq 1 - \exp\left(-\alpha\log\left(\frac{1}{1-|z|}\right)\right) \\ &= 1 - (1-|z|)^\alpha, \end{aligned}$$

which completes the proof. \square

3.3. Separated sets. So far, we have only used the Lipschitz property of our embeddings from \mathbb{D} into \mathbb{B}_d . To make use of the fact that they are also bounded below, we will consider separated sets in the two metric spaces. This is again similar to Rochberg's arguments in [21] in the isometric setting, but some modifications are necessary.

Let (X, d) be a metric space and let $\varepsilon > 0$. We say that a subset $D \subset X$ is ε -separated if any two distinct points in D have distance at least ε , i.e. $d(x, y) \geq \varepsilon$ for all $x, y \in D$ with $x \neq y$. Given a subset $S \subset X$ and $\varepsilon > 0$, we let

$$N(S, d, \varepsilon) = \sup\{|D| : D \subset S \text{ is } \varepsilon\text{-separated}\}.$$

These notions are useful for studying mappings that are bounded below because of the following obvious lemma.

Lemma 3.6. *Let (X, d_X) and (Y, d_Y) be metric spaces and let $f : X \rightarrow Y$. Suppose that there exists a constant $m > 0$ such that $d_Y(f(x), f(y)) \geq md_X(x, y)$ for all $x, y \in X$. Then, for any $S \subset X$, we have*

$$N(f(S), d_Y, m\varepsilon) \geq N(S, d_X, \varepsilon).$$

Proof. If $D \subset S$ is ε -separated, then $f(D) \subset f(S)$ is $m\varepsilon$ -separated. \square

Let C_r denote the circle of radius r around 0 in the complex plane. Our next goal is to establish a lower bound for $N(C_r, \delta, \varepsilon)$, that is, we wish to find large subsets of C_r that are ε -separated in the δ -metric. The following lemma reduces the task of checking whether certain subsets of C_r are ε -separated to checking distances between adjacent points.

Lemma 3.7. *Let $0 < r < 1$, let $0 \leq \theta_1 < \theta_2 < \dots < \theta_n \leq \pi$ and let*

$$D = \{re^{i\theta_1}, \dots, re^{i\theta_n}\}.$$

Then D is ε -separated with respect to δ if and only if $\delta(re^{i\theta_k}, re^{i\theta_{k+1}}) \geq \varepsilon$ for all $1 \leq k \leq n-1$.

Proof. Necessity is clear. To prove sufficiency, by rotation invariance of the metric δ , it suffices to show that

$$[0, \pi] \rightarrow [0, \infty), \quad t \mapsto \delta(re^{it}, r),$$

is increasing. From (4), we see that

$$1 - \delta(re^{it}, r)^2 = \frac{|\log(1 - r^2 e^{it})|^2}{\log(1 - r^2)^2},$$

so it even suffices to show that for each $s \in (0, 1)$, the function

$$f : [0, \pi] \rightarrow [0, \infty), \quad t \mapsto |\log(1 - se^{it})|^2,$$

is decreasing.

Writing $f(t) = \log(1 - se^{it}) \log(1 - se^{-it})$, a straightforward calculation shows that

$$f'(t) = \frac{2s}{|1 - se^{it}|^2} \operatorname{Im}(\log(1 - se^{it})(s - e^{-it})).$$

We finish the proof by showing that for each $t \in [0, \pi]$, the function

$$h : [0, 1) \rightarrow \mathbb{R}, \quad s \mapsto \operatorname{Im}(\log(1 - se^{it})(s - e^{-it}))$$

is bounded above by 0. To this end, notice that $h(0) = 0$, and by another small computation,

$$h'(s) = \operatorname{Im}(\log(1 - se^{it})) \leq 0$$

for all $t \in [0, \pi]$ and all $s \in [0, 1)$, because $1 - se^{it}$ belongs to the closed lower half plane for these values of s and t . Hence, h is decreasing in s , so $h(s) \leq 0$ for all $s \in [0, 1)$, as asserted. \square

The following lemma will allow us to place sufficiently many ε -separated points on C_r as r approaches 1.

Lemma 3.8. *For $0 \leq r < 1$, let $\theta(r) = \sqrt{1 - r}$. Then*

$$\lim_{r \rightarrow 1} \delta(re^{i\theta(r)}, r) = \sqrt{\frac{3}{4}}.$$

Proof. Note that

$$1 - \delta(re^{i\theta(r)}, r)^2 = \frac{|\log(1 - r^2e^{i\theta(r)})|^2}{\log(1 - r^2)^2},$$

so we have to show that

$$\lim_{r \rightarrow 1} \frac{|\log(1 - r^2e^{i\theta(r)})|}{-\log(1 - r^2)} = \frac{1}{2}. \quad (6)$$

Since the imaginary part of \log is bounded, we see that

$$\begin{aligned} \lim_{r \rightarrow 1} \frac{|\log(1 - r^2e^{i\theta(r)})|}{-\log(1 - r^2)} &= \lim_{r \rightarrow 1} \frac{|\operatorname{Re} \log(1 - r^2e^{i\theta(r)})|}{-\log(1 - r)} \\ &= \lim_{r \rightarrow 1} \frac{\log |1 - r^2e^{i\theta(r)}|^2}{2 \log(1 - r)}. \end{aligned} \quad (7)$$

The Taylor series expansion of cosine shows that

$$r \mapsto |1 - r^2e^{i\theta(r)}|^2 = 1 - 2 \cos(\sqrt{1 - r})r^2 + r^4$$

extends to a function h that is differentiable at $r = 1$ and satisfies $h(1) = 0$ and $h'(1) = -1$. Thus, $|1 - r^2 e^{i\theta(r)}|^2 / (1 - r)$ converges to 1 as $r \rightarrow 1$, and so

$$\lim_{r \rightarrow 1} \frac{\log |1 - r^2 e^{i\theta(r)}|^2}{2 \log(1 - r)} = \lim_{r \rightarrow 1} \frac{\log \frac{|1 - r^2 e^{i\theta(r)}|^2}{1 - r} + \log(1 - r)}{2 \log(1 - r)} = \frac{1}{2}.$$

In combination with (7), this proves (6). \square

We are now able to establish the desired lower bound for $N(C_r, \delta, \varepsilon)$.

Lemma 3.9. *Let $C_r = \{z \in \mathbb{C} : |z| = r\}$. If $\varepsilon < \sqrt{3/4}$, then there exists $r_0 < 1$ such that*

$$N(C_r, \delta, \varepsilon) \geq \frac{1}{\sqrt{1 - r}}$$

for all $r_0 < r < 1$.

Proof. Let $\theta(r) = \sqrt{1 - r}$, let $N(r) = \lfloor \frac{\pi}{\sqrt{1 - r}} \rfloor$ and let

$$D(r) = \{r, r e^{i\theta(r)}, \dots, r e^{iN(r)\theta(r)}\}.$$

Observe that $D(r) \subset C_r$ and $|D(r)| \geq \frac{\pi}{\sqrt{1 - r}}$.

By Lemma 3.8, there exists $r_0 < 1$ such that

$$\delta(r e^{i\theta(r)}, r) \geq \varepsilon \quad \text{for all } r \in [r_0, 1).$$

Rotational invariance of δ and Lemma 3.7 now show that $D(r)$ is ε -separated for $r \geq r_0$. Therefore,

$$N(C_r, \delta, \varepsilon) \geq |D(r)| \geq \frac{1}{\sqrt{1 - r}}. \quad \square$$

Finally, we require the following upper bound for the number of points in a ball that are separated with respect to the pseudohyperbolic metric. The result is due to Duren and Weir; see [11, Lemma 5].

Lemma 3.10. *Let $d \in \mathbb{N}$, let $0 < r < 1$ and let $B_r = \{z \in \mathbb{C}^d : \|z\| \leq r\}$. Then*

$$N(B_r, \rho, \varepsilon) \leq \left(\frac{2}{\varepsilon} + 1\right)^{2d} \frac{1}{(1 - r^2)^d}$$

for all $\varepsilon > 0$. \square

3.4. Proof of main result. We are now in position to prove the main result. In light of Corollary 3.3, the following result implies Theorem 1.1.

Theorem 3.11. *For any finite d there does not exist a bi-Lipschitz map from $(\mathbb{D}, \delta_{\mathbb{D}})$ into $(\mathbb{B}_d, \delta_{H_d^2})$.*

Proof. Suppose towards a contradiction that there exists a bi-Lipschitz map $f : \mathbb{D} \rightarrow \mathbb{B}_d$ for some $d < \infty$. Since biholomorphic automorphisms of \mathbb{B}_d are isometries with respect to the pseudohyperbolic metric, we may assume without loss of generality that $f(0) = 0$.

As before, let $C_r = \{z \in \mathbb{C} : |z| = r\}$ and $B_s = \{z \in \mathbb{C}^d : \|z\| \leq s\}$. Applying Proposition 3.5 with $\alpha = 1/(2d+1)$ we find $r_0 < 1$ such that $f(C_r)$ is contained in $B_{s(r)}$ for all $r_0 < r < 1$, where

$$s(r) = 1 - (1 - r)^{1/(2d+1)}.$$

Lemma 3.9 shows that by increasing r_0 if necessary, we may find $\varepsilon > 0$ such that

$$N(C_r, \delta, \varepsilon) \geq \frac{1}{\sqrt{1-r}} \quad \text{for all } r_0 < r < 1.$$

Assuming that f is bounded below by m , Lemma 3.6 then implies that

$$\frac{1}{\sqrt{1-r}} \leq N(B_{s(r)}, \delta_{H_d^2}, m\varepsilon) \quad \text{for all } r_0 < r < 1. \quad (8)$$

On the other hand, Lemma 3.10 shows that

$$N(B_{s(r)}, \delta_{H_d^2}, m\varepsilon) \leq \left(\frac{2}{m\varepsilon} + 1\right)^{2d} \frac{1}{(1 - s(r)^2)^d} \leq C \frac{1}{(1-r)^{d/(2d+1)}} \quad (9)$$

for all $0 < r < 1$ and some constant $C < \infty$ that does not depend on r . Combining (8) and (9), we arrive at a contradiction. Hence, there does not exist a bi-Lipschitz map from (\mathbb{D}, δ) into (\mathbb{B}_d, ρ) for $d < \infty$. \square

3.5. Weighted Dirichlet spaces. For $a \in (0, 1)$, let \mathcal{D}_a be the reproducing kernel Hilbert space on \mathbb{D} with kernel

$$k_a(z, w) = \frac{1}{(1 - z\bar{w})^a}.$$

These spaces are weighted Dirichlet spaces. It is well known that they are also complete Pick spaces, which follows from the fact that the power series coefficients of $1 - 1/k_a$ are non-negative [19, p. 22]. It is natural to ask if Theorem 1.1 can be extended to these spaces.

Question 3.12. Let $a \in (0, 1)$. Do there exist $d \in \mathbb{N}$ and a map $b : \mathbb{D} \rightarrow \mathbb{B}_d$ that induces a surjective homomorphism

$$\text{Mult}(H_d^2) \rightarrow \text{Mult}(\mathcal{D}_a), \quad \varphi \mapsto \varphi \circ b?$$

It was shown in [13, Corollary 11.9] that for any $a \in (0, 1)$, there does not exist a map $b : \mathbb{D} \rightarrow \mathbb{B}_d$ with $d < \infty$ such that

$$k_a(z, w) = \frac{1}{1 - \langle b(z), b(w) \rangle}.$$

The proof of Theorem 1.1 given here does not generalize to \mathcal{D}_a . In fact, Theorem 3.11 is not true with \mathcal{D}_a in place of \mathcal{D} , as the metric $\delta_{\mathcal{D}_a}$ is equivalent to the pseudo-hyperbolic metric ρ on \mathbb{D} . Indeed, from Equation (3), it follows that

$$a^{1/2}\rho \leq \delta_{\mathcal{D}_a} = \left(1 - (1 - \rho^2)^a\right)^{1/2} \leq \rho.$$

Thus, the identity mapping $(\mathbb{D}, \delta_{\mathcal{D}_a}) \rightarrow (\mathbb{D}, \rho)$ is bi-Lipschitz. Nonetheless, the multiplier algebras of H^2 and of \mathcal{D}_a do not coincide.

It therefore appears that different arguments are needed to answer Question 3.12.

4. Other notions of embedding

The following result shows that Theorem 1.1 also rules out the existence of other types of embedding for the Dirichlet space. We also relate Theorem 1.1 to the point of view taken for instance in [9] and [23]. To this end, let $V \subset \mathbb{B}_d$ and define $H_d^2|_V$ to be the reproducing kernel Hilbert space on V whose reproducing kernel is the restriction of the Drury–Arveson kernel to $V \times V$. Equivalently,

$$H_d^2|_V = \{f|_V : f \in H_d^2\},$$

equipped with the quotient norm.

Proposition 4.1. *Let \mathcal{H} be a reproducing kernel Hilbert space on a set X separating the points of X with reproducing kernel k . Let $d \in \mathbb{N} \cup \{\infty\}$ and let $b : X \rightarrow \mathbb{B}_d$ and $\delta : X \rightarrow \mathbb{C} \setminus \{0\}$ be mappings. Let $V = b(X)$.*

Among the following statements, the implications

$$(i) \Leftrightarrow (i') \Leftrightarrow (i'') \Rightarrow (ii) \Leftrightarrow (ii') \Rightarrow (iii) \Leftrightarrow (iii')$$

hold.

$$(i) \quad k(z, w) = \frac{\delta(z)\overline{\delta(w)}}{1-\langle b(z), b(w) \rangle} \text{ for all } z, w \in X;$$

(i') *the assignment*

$$H_d^2 \rightarrow \mathcal{H}, \quad f \mapsto \delta \cdot (f \circ b),$$

defines a co-isometry;

(i'') *the assignment*

$$H_d^2|_V \rightarrow \mathcal{H}, \quad f \mapsto \delta \cdot (f \circ b),$$

defines a unitary;

(ii) *the assignment*

$$H_d^2 \rightarrow \mathcal{H}, \quad f \mapsto \delta \cdot (f \circ b),$$

defines a surjection;

(ii') *the assignment*

$$H_d^2|_V \rightarrow \mathcal{H}, \quad f \mapsto \delta \cdot (f \circ b),$$

defines a bijection;

(iii) *the assignment*

$$\text{Mult}(H_d^2) \rightarrow \text{Mult}(\mathcal{H}), \quad \varphi \mapsto \varphi \circ b,$$

defines a surjection;

(iii') *the assignment*

$$\text{Mult}(H_d^2|_V) \rightarrow \text{Mult}(\mathcal{H}), \quad \varphi \mapsto \varphi \circ b,$$

defines a bijection.

Proof. The proof consists of routine arguments with reproducing kernels. We sketch the main ideas.

(i) \Rightarrow (i') Let $K(z, w) = \frac{1}{1-\langle z, w \rangle}$ be the reproducing kernel for H_d^2 . Condition (i) implies that

$$\langle k(\cdot, w), k(\cdot, z) \rangle_{\mathcal{H}} = \langle \overline{\delta(w)}K(\cdot, b(w)), \overline{\delta(z)}K(\cdot, b(z)) \rangle_{H_d^2} \quad (z, w \in X),$$

from which it follows that there exists an isometry $V : \mathcal{H} \rightarrow H_d^2$ with

$$Vk(\cdot, w) = \overline{\delta(w)}K(\cdot, b(w)) \quad (w \in X). \quad (10)$$

The adjoint $V^* : H_d^2 \rightarrow \mathcal{H}$ is the map in the statement of (i').

(i') \Rightarrow (i) If T denotes the co-isometry in the statement of (i'), then $V = T^*$ is an isometry satisfying (10), from which (i) follows.

(i') \Leftrightarrow (i'') The restriction map $H_d^2 \rightarrow H_d^2|_V$ is a co-isometry whose kernel is $I(V)$, the space of all functions in H_d^2 vanishing on V . So if the map in (i'') is unitary, then the map in (i') is a co-isometry. Conversely, if the map in (i') is a co-isometry, then its kernel is $I(V)$, so the map in (i'') is unitary.

(i') \Rightarrow (ii) is trivial.

(ii) \Leftrightarrow (ii') follows in the same way as (i') \Leftrightarrow (ii').

(ii') \Rightarrow (iii') Let

$$T : H_d^2|_V \rightarrow \mathcal{H}, \quad f \mapsto \delta \cdot (f \circ b),$$

be the map in (ii'). By the closed graph theorem and the open mapping theorem, T is bounded and has a bounded inverse. Moreover, since \mathcal{H} separates the points of X , surjectivity of T shows that b is injective, hence the inverse of T is given by

$$T^{-1}g = \left(\frac{g}{\delta} \right) \circ b^{-1}.$$

Therefore, if $\varphi \in \text{Mult}(H_d^2|_V)$, then

$$TM_\varphi T^{-1}g = (\varphi \circ b) \cdot g \quad (g \in \mathcal{H}),$$

so the operator $TM_\varphi T^{-1}$ on \mathcal{H} is given by multiplication with $\varphi \circ b$. In particular, $\varphi \circ b \in \text{Mult}(\mathcal{H})$. Similarly, if $\psi \in \text{Mult}(\mathcal{H})$, then $T^{-1}M_\psi T$ is the operator of multiplication by $\psi \circ b^{-1}$ on $H_d^2|_V$, so $\psi \circ b^{-1} \in \text{Mult}(H_d^2|_V)$. Hence (iii') holds.

(iii) \Leftrightarrow (iii') The complete Pick property of H_d^2 shows that the restriction map $\text{Mult}(H_d^2) \rightarrow \text{Mult}(H_d^2|_V)$ is surjective, and its kernel consists of all multipliers vanishing on V . The equivalence of (iii) and (iii') readily follows from this fact. \square

In [23, Section 7.5], Salomon and Shalit asked if there exist $d \in \mathbb{N}$ and $V \subset \mathbb{B}_d$ such that $\text{Mult}(\mathcal{D})$ is isomorphic to $\text{Mult}(H_d^2|_V)$. Using Theorem 1.1, we can also show that this cannot happen.

Theorem 4.2. *There do not exist $d \in \mathbb{N}$ and a subset $V \subset \mathbb{B}_d$ such that $\text{Mult}(\mathcal{D})$ is algebraically isomorphic to $\text{Mult}(H_d^2|_V)$.*

Proof. We use arguments from the study of the isomorphism problem for multiplier algebras of complete Pick spaces to show that any isomorphism must be given by composition with a map $b : \mathbb{D} \rightarrow \mathbb{B}_d$; see for instance [9, Theorem 2.4].

Suppose towards a contradiction that $V \subset \mathbb{B}_d$ for finite d and that

$$\Phi : \text{Mult}(H_d^2|_V) \rightarrow \text{Mult}(\mathcal{D})$$

is an algebraic isomorphism. Let

$$\Psi : \text{Mult}(H_d^2) \rightarrow \text{Mult}(\mathcal{D}), \quad \varphi \mapsto \Phi(\varphi|_V).$$

The complete Pick property of H_d^2 and surjectivity of Φ imply that Ψ is a surjective unital homomorphism. We consider the adjoint Ψ^* between the maximal ideal spaces $\mathcal{M}(\text{Mult}(\mathcal{D}))$ and $\mathcal{M}(\text{Mult}(H_d^2))$. For each $\lambda \in \mathbb{D}$, the character of point evaluation δ_λ belongs to $\mathcal{M}(\text{Mult}(\mathcal{D}))$, and similarly for $\mathcal{M}(\text{Mult}(H_d^2))$. Moreover, we have a map

$$\pi : \mathcal{M}(\text{Mult}(H_d^2)) \rightarrow \overline{\mathbb{B}_d}, \quad \chi \mapsto (\chi(z_1), \dots, \chi(z_d)),$$

with the property that $\pi^{-1}(w) = \{\delta_w\}$ for each $w \in \mathbb{B}_d$; see for instance Lemma 8.1 and Proposition 8.6 in [13].

Let

$$b : \mathbb{D} \rightarrow \overline{\mathbb{B}_d}, \quad \lambda \mapsto (\pi \circ \Psi^*)(\delta_\lambda) = (\Psi(z_1)(\lambda), \dots, \Psi(z_d)(\lambda)).$$

Since Ψ takes values in $\text{Mult}(\mathcal{D})$, the map b is holomorphic. If b were constant, then since $\Psi(z_k) = \Phi(z_k|_V)$, injectivity of Φ would imply that V is a singleton, a contradiction. Hence, b is not constant and therefore takes values in the open ball \mathbb{B}_d by the maximum modulus principle. Since the fibers of π over \mathbb{B}_d are singletons, we see that $\Psi^*(\delta_\lambda) = \delta_{b(\lambda)}$ for all $\lambda \in \mathbb{D}$. Thus, for $\varphi \in \text{Mult}(H_d^2)$ and $\lambda \in \mathbb{D}$, we find that

$$\Psi(\varphi)(\lambda) = \Psi^*(\delta_\lambda)(\varphi) = \delta_{b(\lambda)}(\varphi) = \varphi(b(\lambda)),$$

so

$$\Psi : \text{Mult}(H_d^2) \rightarrow \text{Mult}(\mathcal{D}), \quad \varphi \mapsto \varphi \circ b,$$

is a surjective homomorphism. But according to Theorem 1.1, this is impossible. This contradiction finishes the proof. \square

5. An explicit embedding for the Dirichlet space

Recall from the introduction that

$$k(z, w) = \frac{1}{zw} \log \left(\frac{1}{1 - z\bar{w}} \right) = \sum_{n=0}^{\infty} (n+1)^n (z\bar{w})^n$$

denotes the reproducing kernel of the Dirichlet space and that the real numbers $(c_n)_{n=1}^\infty$ are defined by the power series identity

$$\sum_{n=1}^{\infty} c_n (z\bar{w})^n = 1 - \frac{1}{k(z, w)}.$$

An argument from the work of Kluyver [17] yields an explicit formula for c_n . This is Proposition 1.2, which we restate for the reader's convenience.

Proposition 5.1. *For $n \geq 1$, we have*

$$c_n = \int_0^1 t \frac{\Gamma(n-t)}{\Gamma(n+1)\Gamma(1-t)} dt \geq 0.$$

Proof. We reproduce the computation from [17]. Let $z \in \mathbb{D}$ and notice that

$$\frac{d}{dt} \frac{(1-z)^t}{\log(1-z)} = (1-z)^t,$$

hence

$$\sum_{n=1}^{\infty} c_n z^n = 1 + \frac{z}{\log(1-z)} = 1 - \int_0^1 (1-z)^t dt.$$

We can expand the integrand into a binomial series

$$(1-z)^t = \sum_{n=0}^{\infty} \binom{t}{n} (-1)^n z^n,$$

which converges uniformly in $t \in [0, 1]$ for fixed $z \in \mathbb{D}$ because the binomial coefficients are bounded in modulus by 1. Therefore,

$$\sum_{n=1}^{\infty} c_n z^n = \sum_{n=1}^{\infty} z^n (-1)^{n+1} \int_0^1 \binom{t}{n} dt,$$

so comparing coefficients, we conclude that for all $n \geq 1$,

$$\begin{aligned} c_n &= (-1)^{n+1} \int_0^1 \binom{t}{n} dt = \frac{1}{n!} \int_0^1 t(1-t)(2-t) \dots (n-1-t) dt \\ &= \int_0^1 t \frac{\Gamma(n-t)}{\Gamma(n+1)\Gamma(1-t)} dt. \end{aligned}$$

Clearly, the integrand is non-negative, so $c_n \geq 0$ for all $n \geq 1$. \square

The coefficients $G_n = (-1)^{n-1} c_n$ appear in the literature under the name Gregory coefficients; see [8] for historical remarks and many results regarding these coefficients. In particular, the asymptotic behavior of the Gregory coefficients, and hence of (c_n) , is well understood; see Equation 52 in [8]. In the study of the Dirichlet space, knowledge about the asymptotic behavior of (c_n) is sometimes useful; see for instance [24, p. 126]. Here, we sketch how the formula in Proposition 5.1 can be used to determine the first-order behavior of (c_n) , which also follows from the finer analysis in [8].

Corollary 5.2. *The asymptotic relation*

$$c_n \sim \frac{1}{n \log(n)^2}$$

holds.

Proof. To determine the asymptotic behavior of the integrand in Proposition 5.1 as $n \rightarrow \infty$, we use the following inequality of Wendel [25]:

$$\left(\frac{x}{x+s}\right)^{1-s} \leq \frac{\Gamma(x+s)}{x^s \Gamma(x)} \leq 1 \quad \text{for all } x \in \mathbb{R}, s \in [0, 1] \quad (11)$$

In combination with the functional equation $\Gamma(x+1) = x\Gamma(x)$, this formula shows that

$$\lim_{n \rightarrow \infty} \frac{\Gamma(n-t)}{\Gamma(n+1)} (n+1)^{t+1} = 1$$

uniformly in $t \in [0, 1]$, so by Proposition 5.1, we find that

$$c_n \sim \int_0^1 t(n+1)^{-t-1} \frac{1}{\Gamma(1-t)} dt. \quad (12)$$

The second inequality in (11), applied with $x = 1$, shows that $s\Gamma(s) \leq 1$ for $s \in [0, 1]$. Together with the basic inequality $\Gamma(s) \geq 1$ for $s \in [0, 1]$, we find that

$$\int_0^1 t(1-t)(n+1)^{-t-1} dt \leq \int_0^1 t(n+1)^{-t-1} \frac{1}{\Gamma(1-t)} dt \leq \int_0^1 t(n+1)^{-t-1} dt.$$

Both of these integrals can be computed explicitly, for instance using integration by parts, which shows that both have asymptotic behavior $\sim n^{-1} \log(n)^{-2}$. By (12), the sequence (c_n) therefore has the same asymptotic behavior. \square
